ABSTRACT

This article is the continuation of our articles, published on the same site IJARIE which have a reference ISSN (O): 2395-4396, Paper id: 11241, whose title is the contribution to the study of high-compact fluid concretes: formulations and characterizations; and a Paper id 11270, a title of Modelling of fluid concretes by experimental designs.

After the formulation and modeling of the three ordinary concretes and twenty-one high-compact fluid concretes, the study and the price analysis of these concretes were carried out.

These concretes are formulated from the same materials, but the quantity and dosage that make them different. We referred to the quantities of gravel, sand, cement, water and admixture, to be able to evaluate the unit prices of concretes.

The unit prices of concretes generally depend on the price of materials, on the wages needed to pay for labour and on the amount of money that must be set aside to provide for the depreciation of materials and tools. Various overheads are also included in the unit prices.

In order to make a decision on the use of concrete types on the construction site, the ABC analysis allows evaluating concretes that have the lowest prices but good qualities.

Keyword: Concrete, Unit Prices, Materials, Fees, Disbursements, PARETO Diagram.

1. INTRODUCTION

To highlight the research we have done on the formulation and mathematical modeling of fluid concretes with high compactness, we will study, for the continuation; the studies of the price of the confections of the various concretes per cubic meter.

We study in tables the unit prices of concretes by detailing the costs of materials, the costs of labour and the costs of materials of these various concretes. PARETO's diagrams and analysis are used to make a decision on the use of concrete

2. CONCRETE PRICE STUDIES

2.1. Unit Price

The unit price of a concrete is given by the relation:
$$PU \approx \frac{D \times K_1}{R}$$

D: the dry disbursements that derive from the combination of the unit prices of materials, equipment and labour. It is the totality of all expenses for the purchase of materials, for the wages of the executing workers and for the rental or depreciation of materials or tools.

K_1 : le coefficient de déboursé appelé traditionnellement coefficient d'adjudication "c". This is the coefficient which allows the influence of construction costs, overheads and costs proportional to the selling price and of course the profit to be introduced into the unit prices and which is detailed below.

The disbursement coefficient K_1 is defined by the following formula:

$$K_1 \approx \frac{\left(\frac{1+A_1}{100}\right)\left(\frac{1+A_2}{100}\right)}{1 - \left(\frac{A_3}{100} \times \left(1 + \frac{TVA}{100}\right)\right)}$$

With A_1 : Overheads proportional to disbursements $A_1 = a_1 + a_2 + a_3$

(Agency and patent fees (a_1), Building site costs (a_2), Study costs (a_3), Assurance (a_4))

A_2 : Gross profit and financial costs proportional to the cost price of the company $A_2 = a_5 + a_6 + a_7 + a_8$

(Bénéfice net et impôt sur le bénéfice (a_5), Aléas technique (a_6), Aléas de révision des prix (a_7), Frais financiers (a_8))

A_3 : Fee proportional to the settlement price with tax $A_3 = a_9$

(Frais de siège (a_9))

The calculation detail of K_1 is given in the following table 1:

Table 1: Calculation details for disbursement coefficient K_1

| Overheads proportional to disbursements A1 | | | | Gross profit and expenses Financial A2 | | | | Fees proportional to settlement prices with Tax A3 |
|--|-----|----|----|---|----|----|----|---|
| a1 | a2 | a3 | a4 | a5 | a6 | a7 | a8 | a9 |
| 3% | 10% | 4% | 5% | 10% | 4% | 3% | 2% | 0 |
| A1 = 22% | | | | A2 = 19% | | | | A3 = 0 |
| K1 = 1.45 | | | | | | | | |

If the concrete batching plant company has its headquarters in Madagascar $a_9 = 0$

2.2. Summary of the dosages of each constituent of concretes

The dosages of each constituent of three ordinary concretes BO1, BO2 and BO3 in one cubic meter are given in the following table 2:

Table -2 : Doses of each constituent of BO1 and BO2 in one cubic metre

| BO1 | | | | BO2 | | | | | | BO3 | | | | | |
|-----------|----------|-------------|------------|-----------|----------|------------|-------------|------------|-----------|-----------|----------|------------|-------------|------------|-----------|

2. GENERAL INFORMATION ON THE ABC ANALYSIS

2.1. Principle of ABC analysis

The PARETO diagram allows you to visualize the relative importance of the different parts or categories of a previously analyzed and quantified set in the form of a ranking and hierarchy.

The ABC analysis or PARETO analysis allows to highlight the prices of concretes which have the lowest costs but good qualities in order to guide the action of selling or use on site. The principle is presented in the following figure 1.

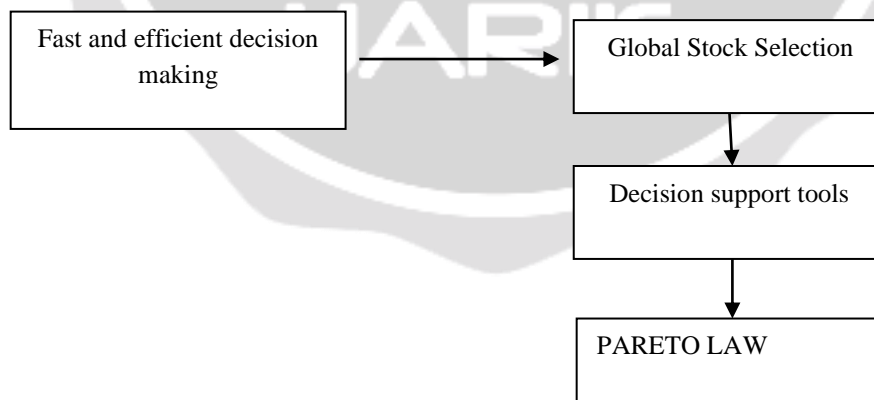

Figure 1: Decision-making

The elements will be ranked in order of importance by indicating the percentages for a given criterion, which requires a three-step approach:

- Define the nature of the elements to be ranked
- Choose the ranking criterion
- Define study boundaries and classify elements

By cumulating the decreasing values of the criterion studied, the ABC curve or PARETO curve shows three zones, hence the name "ABC curve";

Zone A: 20% of the number of elements represent 80% of the criterion studied.

Zone B: the 30% more elements represent 15% more than the criterion studied;

Zone C: The remaining 50% of elements represent only 5% of the criterion studied.

2.3. PARETO diagram

The information given in the table allows you to transfer in an orthonormal marker

- In abscissa, the elements studied in cumulative %,
- On the Y-axis, the cumulative % values of the criterion.

By connecting the points thus obtained, an ascending curve must appear on which the limits of the three groups must be indicated.

2.4. Methodical approach

For a given sector or system, the application of Pareto's law requires several steps:

- Step 1: Make the analysis table which consists of the following 6 columns:

Column n°1: order n° of the products studied;

Column n°2: names or references of the products studied (to be filled in after column n°3);

Column n°3: values of the chosen criterion in descending order;

Column n°4: cumulative increasing values of the chosen criterion;

Column 5: cumulative increasing values of the chosen criterion in percentage;

Column n°6: cumulative percentages of the products studied.

The structure of the table is shown as follows:

Table 8: Table structure of the ABC analysis

| Product number | order | References of the studied products | Criteria descending order | Increasing cumulative criteria | Cumulative increasing criteria % | Cumulative percentage of products studied |
|----------------|-------|------------------------------------|---------------------------|--------------------------------|----------------------------------|---|
| | | | | | | |

- Step 2: Graphing the data

In an orthonormal marker, report the cumulative percentages of the products studied on the abscissa, and the values of the chosen criterion increasing in percentage on the ordinate;

Draw the curve connecting the points obtained.

- Step 3: Draw a conclusion and propose a decision

The PARETO table is then represented as follows (Table 9)

Table 9: PARETO's table on concrete unit prices

| ORDER NO. | REFERENCES | PU DES BETONS | UNIT PRICE CUMULATIVE GROWING | UNIT PRICE CUMULATIVE % | REFERENCES CCUMULATIVE % | ZONE |

Ce qui nous donne la figure suivante (Figure 39)

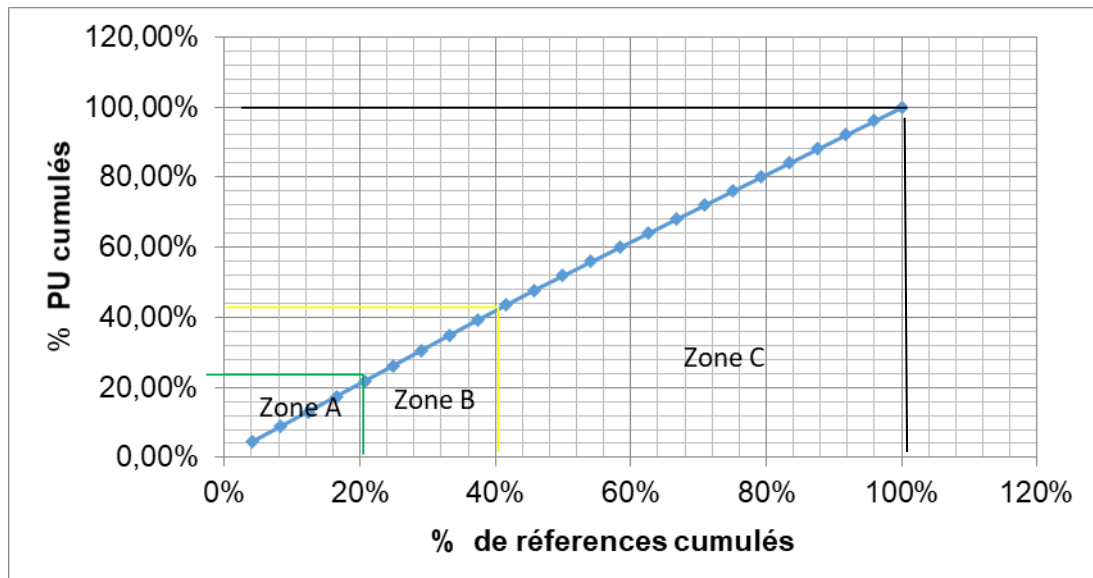

Figure 1: Distribution of zones A, B and C of concrete unit prices

5. CONCLUSION

BFLs generally bring labour savings: no vibration energy and a reduction in the number of workers.

Concrete in zone A (BFL9 , BFL7, BFL17, BFL15, BFL19) and in zone B (BFL13 , BFL11, BFL21, BO1, BFL1) have high costs. This is normal since they have a high cement dosage of 400 Kg. Among these concretes of type Q400, it is preferable to make the fluid concrete BFL11 for the construction of an engineering structure (prestressed concrete bridge,...). This concrete formulated by experimental designs has a low cost but a high compressive strength at 28 days. BFL1 and BO1 are formulated with the same type of materials. The total cost to make one cubic meter of BFL1 fluid concrete is 9994 Ar less than BO1. BFL1 fluid concrete not only provides good compressive strength at 28 days (35.8 MPa for BFL1 and 23.2 MPa for BO2), but also a cost reduction of up to 1.73% compared to BO1. The concretes in zone C are concretes dosed at 350 Kg of cement. These concretes are formulated from identical materials. The target concrete is BFL20 fluid concrete: it has a 28-day compressive strength of 36.1 MPa, but a low cost. Compared to BO3, their cost is 32336 Ar in one cubic meter. Therefore, for a building structure that requires 1000 m³ of concrete, there will be a cost reduction of 32,336,000 Ar, when using BFL20 instead of BO3. The BO3 formula is the most commonly used formula on the building site.

But let's not forget also that BFLs have many advantages on durability (more compact), workability and physical qualities. It is therefore possible to produce a concrete that is more durable and easier to work with, at a lower cost compared to BO.
