ABSTRACT: Given any real or complex Singular & non-singular square matrix, the inverse of the matrix can be found efficiently.

KEYWORDS: matrix, inverse, inversion, nonsingular, square, algorithm, iterative, fast, time complexity, efficient.

I. INTRODUCTION

To reduce the computational complexity of matrix inversion, which is the majority of processing in many practical applications, efficient algorithms for calculating the inverse of an arbitrary nonsingular matrix are presented. Based on the algorithms V[1-3] and some related research [4-5], this compact algorithm may improve the time complexity and provide an even greater computational savings. The following are the algorithm, source code and some typical example with simple error checking.

II. ALGORITHM

The presented algorithm consists of the following steps:

Step 1 Initialization:

Let M be a non-singular $n \times n$ matrix. Let I be an $n \times n$ identity matrix.

$n = \text{length}(M); I = \text{eye}(n); N = [1:n]; M = M - I; W = I;$

Step 2 Iterative operations:

```
for k = 1:n; K = [1:k];
    W(N,K) = W*(I(N,K)-M(N,k)*W(k,K)/(1+W(k,N)*M(N,k)));
end;
```

Step 3 Outputs:

Print out the result of the inverse of M, which is W.

III. MATLAB SOURCE CODE

```

Function W = inv_fc(M)
% Compute the inverse of non-singular square matrix
% Error checking: W*M = I
n = length (M); N = [1:n]; I = eye(n); M = M-I; W = I;for k = 1:n;
K = [1:k];
W(N,K) = W*(I(N,K)-M(N,k)*W(k,K)/(1+W(k,N)*M(N,k)));
End;

```

IV. TYPICAL EXAMPLES

V. CONCLUSION

The speed of computation to get the desired matrix inverse in an algorithm is related to the total number of elementary multiplication/division operations. For a given square matrix of order n , the total number of EMDO used for the presented compact code is computed to be $(n^4+n^3+2n^2+2n)/2$.

It is also worth noting that the line inside the for loop of this function may also be replaced by
 $W(K,N)=(I(K,N)-W(K,k)*M(k,N)/(1+M(k,N)*W(N,k)))*W.$

MATLAB simulations show that these algorithms are valid.
